**AMENDMENTS TO THE DRAWINGS:**

There are no amendments to the drawings presented herewith.

Appl. No.: 10/709,866  
Amdt. Dated: 6/15/2008  
Reply to Office action of: 12/14/2007

**REMARKS/ARGUMENTS**

Claims 1 – 17 remain in this application. Claim 1 has been amended to correct a minor typographical error.

No new matter has been introduced by these amendments to the claims.

Claims 1, 4 – 8, 10 – 12, 14, and 17 were rejected under 35 U.S.C. 103(a) as being unpatentable over Nelson (6,488,723) in view of Lyben (2,849,304). Specifically, the Examiner states:

Nelson discloses a motor fuel additive composition comprising (a) a fuel conditioner component and (b) a detergent component. The fuel conditioner (a) comprises (i) from 2 to 50 percent by weight of a polar oxygenated hydrocarbon compound and (ii) from about 2 to about 50 percent by weight of an oxygenated compatibilizing agent. The detergent component (b) is selected from the group consisting of (i) a reaction product of a substituted hydrocarbon (A) and an amino compound (B), and (ii) a polybutylamine or polyisobutylamine (see abstract). The polar oxygenated hydrocarbon has an average molecular weight of from about 200 to about 500, and acid number of about 25 to 175, and a saponification number of about 75 to about 200 (col. 7, lines 11 – 33). The oxygenated compatibilizing agent has a solubility parameter of from about 7.0 to about 14.0 and moderate to strong hydrogen-bonding capacity (col. 7, lines 53 – 62). The hydrocarbon compound (A) of the detergent component is a substituted hydrocarbon of the formula R<sub>1</sub>—X wherein R<sub>1</sub> is a hydrocarbyl radical having a molecular weight in the range of about 150 to 10,000 and X is selected from the group consisting of halogens, succinic anhydride and succinic dibasic acid (col. 4, lines 52 – 65). The amino compound (B) is of the formula H—(NH—(A)<sub>m</sub>)<sub>n</sub>—Y—R<sub>2</sub> wherein Y, A, m, n, and R<sub>2</sub> are identical to those in the instant claim 8 (col. 5, lines 1 – 21). The polybutylamine or polyisobutylamine is identical to that in instant claim 8 (col. 6, lines 30 – 46). Further, the composition includes other additives such as methyl tertiary butyl ether (MTBE) and ethyl tertiary butyl ether (ETBE), alcohols such as methanol or ethanol, and additives that are “typically

employed in motor fuels" such as a common anti-knock additive, tetraethyl lead (col. 9, lines 56 – 60). Nelson also discloses examples wherein the additive composition was added to a base fuel in amounts between 40 ppm and 1000 ppm (col. 10, lines 44 – 50; col. 11, lines 14 – 20).

Nelson is silent with respect to the composition comprising a lead scavenger compound.

Lyben discloses leaded motor fuels containing anti-knock agents such as tetraethyl lead, wherein a means for removing the lead-containing products of combustion known in the art includes providing an alkyl halide lead scavenger such as ethylene dibromide and ethylene dichloride. Further, the process known as scavenging proves to be beneficial in that the lead scavengers, when co-present with the anti-knock agents reacted in a combustion chamber of an engine with the combustion products of the antiknock agents to form volatile lead halides, which in turn are efficiently removed from the combustion chamber during the exhaust cycle (col. 1, lines 20 – 40).

It would therefore have been obvious to one of ordinary skill in the art to combine the teachings of Nelson and Lyben, and include ethylene dibromide or dichloride as a lead scavenger in the additive composition of Nelson, which contains tetraethyl lead, an anti-knock agent. The scavenger would be beneficial to the composition in aiding removal of lead-containing products of combustion.

Regarding claims 6 and 7, although Nelson and Lyben do not disclose the addition of the additive composition to the base fuel simultaneously or after other additives, it is noted that "[E]ven though product-by-process claims are limited by and defined by the process, determination of patentability is based on the product itself. The patentability of a product does not depend on its method of production. If the product in the product-by-process claim is the same as or obvious from a product of the prior art, the claim is unpatentable even though the prior product was made by a different process", *In re Thorpe*, 777 F.2d 695, 698 227 USPQ 964, 966 (Fed. Cir. 1985). Further, "although produced by a different process, the burden shifts to applicant to come forward with evidence establishing an unobvious difference between the claimed product and the prior art product", *In re Marosi*,

Appl. No.: 10/709,866  
Amdt. Dated: 6/15/2008  
Reply to Office action of: 12/14/2007

710 F.2d 798, 802, 218 USPQ 289, 292 (Fed. Cir. 1983).  
See MPEP 2113.

Therefore, absent evidence of criticality regarding the presently claimed addition of the additive composition to the base fuel simultaneously or after other additives and given that Nelson and Lyben meet the requirements of the claimed composition, Nelson and Lyben clearly meet the requirements of present claims 6 and 7.

Applicant respectfully traverses these rejections. The key to Applicant's invention is providing a leaded motor fuel additive composition for bulk fuel addition. More particularly, this invention relates to a motor fuel additive composition comprising: (a) a fuel conditioner component comprising (i) a polar oxygenated hydrocarbon compound, and (ii) an oxygenated compatibilizing agent; (b) an alkyl lead compound; and (c) a lead scavenger compound for use in bulk production of motor fuels containing alkyl lead allowing lower levels of alkyl lead while improving performance and decreasing ORI.

A fair reading of the Nelson ('723) reference discloses an additive package for motor fuels having any anti-knock materials previously blended into the base motor fuel before addition of the additive package of Nelson ('723). Because of the unpredictable nature of organic compositions, adding the tetramethyl and the additive package simultaneously with, or after other additives into the fuel as opposed to adding these components to the fuel before introduction of other additive package is not obvious. This is confirmed by the fact that the amount of alkyl lead required while maintaining the desired level of anti-knock performance and ORI reduction is realized with lower amounts of alkyl lead when it is mixed into the additive package of the claimed invention as opposed to being mixed into the fuel before or after mixing in the claimed additive package.

There is nothing in the Nelson ('723) reference which discloses, teaches or suggests to one skilled in the art how to modify the reference to provide for introducing the alkyl lead and the additive package simultaneously with, or after other additives into the fuel as opposed to adding these components to the fuel before introduction of other additive packages.

A fair reading of the Lyben ('304) reference discloses the use of particular lead scavenger compounds which are taught to be more efficient than the alkyl lead compounds taught in Applicants' claimed invention (Col. 2, line 46 – Col. 3, line 7). The

Lyben ('304) reference also teaches that while bromine or chloride atoms may be attached to some of the carbon atoms in these claimed compounds they may not be attached to carbon atoms containing the active portions of the molecule (Col. 3, lines 8 – 24). Thus, this reference clearly teaches away from the use of the very lead compounds claimed in Applicants' invention.

There is nothing in the Lyben ('304) reference which discloses, teaches or suggests to one skilled in the art how to modify the reference to provide for the use of the additive composition of Nelson ('723), nor the unexpected ability to reduce the amount of alkyl lead compound required while retaining desired levels of ORI reduction and anti-knock.

Clearly, when viewed in this light the Nelson ('723) reference nor the Lyben ('304) reference disclose, teach, or suggest the use of an additive composition allowing the use of lower than expected levels of alkyl lead compounds claimed in Applicants' invention while retaining engine performance as claimed in Applicants' present invention.

Claims 2 – 3, 9, 13, and 15 – 16 were rejected under 35 U.S.C. 103(a) as being unpatentable over Nelson in view of Lyben, and further in view of Carlson (3,083,088). Specifically, the Examiner states:

The disclosure of Nelson and Lyben in paragraph 5 above is herein incorporated by reference.

Both Nelson and Lyben are silent with respect to the amount of alkyl lead compound included in the composition.

Carlson discloses a motor fuel composition including alkyl lead anti-knock agents such as tetraethyl lead, included in low amounts within the range of about 0.5 to about 3.0 grams per gallon. The effectiveness of tetraethyl lead to rise the octane number and suppress knocking decreases with increasing quantities. Therefore, a small amount in the range disclosed proves to be beneficial to the composition (col. 1, lines 10 – 35).

It would have been obvious to one of ordinary skill in the art at the time of the invention by applicant to combine the teachings of Nelson, Lyben, and Carlson in order to utilize the benefits of tetraethyl lead at low amounts.

Applicant respectfully traverses these rejections. The key to Applicant's invention, as mentioned above, is providing a leaded motor fuel additive composition for bulk fuel addition. More particularly, this invention relates to a motor fuel additive composition comprising: (a) a fuel conditioner component comprising (i) a polar oxygenated hydrocarbon compound, and (ii) an oxygenated compatibilizing agent; (b) an alkyl lead compound; and (c) a lead scavenger compound for use in bulk production of motor fuels containing alkyl lead allowing lower levels of alkyl lead while improving performance and decreasing ORI.

A fair reading of the Nelson ('723) reference, as mentioned above, discloses an additive package for motor fuels having any anti-knock materials previously blended into the base motor fuel before addition of the additive package of Nelson ('723). Because of the unpredictable nature of organic compositions, adding the tetramethyl and the additive package simultaneously with, or after other additives into the fuel as opposed to adding these components to the fuel before introduction of other additive package is not obvious. This is confirmed by the fact that the amount of alkyl lead required while maintaining the desired level of anti-knock performance and ORI reduction is realized with lower amounts of alkyl lead when it is mixed into the additive package of the claimed invention as opposed to being mixed into the fuel before or after mixing in the claimed additive package.

There is nothing in the Nelson ('723) reference which discloses, teaches or suggests to one skilled in the art how to modify the reference to provide for introducing the alkyl lead and the additive package simultaneously with, or after other additives into the fuel as opposed to adding these components to the fuel before introduction of other additive packages.

A fair reading of the Lyben ('304) reference, as mentioned above, discloses the use of particular lead scavenger compounds which are taught to be more efficient than the alkyl lead compounds taught in Applicants' claimed invention (Col. 2, line 46 – Col. 3, line 7). The Lyben ('304) reference also teaches that while bromine or chloride atoms may be attached to some of the carbon atoms in these claimed compounds they may not be attached to carbon atoms containing the active portions of the molecule (Col. 3, lines 8 – 24). Thus, this reference clearly teaches away from the use of the very lead compounds claimed in Applicants' invention.

Appl. No.: 10/709,866  
Amdt. Dated: 6/15/2008  
Reply to Office action of: 12/14/2007

There is nothing in the Lyben ('304) reference which discloses, teaches or suggests to one skilled in the art how to modify the reference to provide for the use of the additive composition of Nelson ('723), nor the unexpected ability to reduce the amount of alkyl lead compound required while retaining desired levels of ORI reduction and anti-knock.

A fair reading of the Carlson ('088) reference discloses the use of aromatic substituted esters as an additional compound to raise the octane number, and help suppress knocking in leaded gasoline fuels (Col. 1, lines 51 – 60). This reference realizes that alkyl lead compounds have a limit to effectiveness that decreases with increased amounts of these alkyl lead compounds in gasoline and the fact that they create deposits in the combustion chambers. Instead of scavenging these deposits this reference teaches to add a substitute octane enhancer in addition to the use of alkyl lead compounds. Thus, this reference clearly teaches away from the sole use of the very lead compounds claimed by Applicant's invention and how to reduce the amount of these alkyl lead compounds without the addition of other anti-knock compounds.

There is nothing in the Carlson ('088) reference which discloses, teaches or suggests to one skilled in the art how to modify the reference to provide for the use of the additive composition of Nelson ('723) and the novel organo lead compounds of Lyben ('304), or the unexpected ability to reduce the amount of alkyl lead compound required while retaining desired levels of ORI reduction and anti-knock, in combination with a second class of octane enhancer/anti-knock compounds.

Claims 1 – 17 are rejected under 35 U.S.C. 103(a) as being unpatentable over Nelson in view of Carlson (3,083,088). Specifically, the Examiner states:

The disclosure of Nelson is above and is herein incorporated by reference.

Nelson is silent with respect to the composition comprising a lead scavenger compound, and the amount of anti-knock additive, tetraethyl lead, included in the composition.

Carlson discloses a motor fuel composition including alkyl lead anti-knock agents such as tetraethyl lead, and alkyl halide lead scavengers such as ethylene dibromide and dichloride. Tetraethyl lead is included in low amounts within the range of about 0.5 to 3.0 grams per gallon. The effectiveness of tetraethyl lead to raise the octane number and suppress knocking decreases with

increasing quantities. Therefore, a small amount in the range disclosed proves to be beneficial (col. 1, lines 10 – 35). The lead scavengers, such as ethylene dibromide and ethylene dichloride, impart useful properties to the fuel in its use in internal combustion engines (col. 3, lines 56 – 71).

It would have been obvious to one of ordinary skill in the art at the time of the invention by applicant to combine the teachings of Nelson and Carlson in order to utilize the benefits of alkyl lead anti-knock agents and alkyl halide lead scavengers as disclosed in Carlson.

Regarding claims 6 and 7, although Nelson and Carlson do not disclose the addition of the additive composition to the base fuel simultaneously or after other additives, it is noted that “[E]ven though product-by-process claims are limited by and defined by the process, determination of patentability is based on the product itself. The patentability of a product does not depend on its method of production If the product in the product-by-process claim is the same as or obvious from a product of the prior art, the claim is unpatentable even though the prior product was made by a different process”, *In re Thorpe*, 777 F.2d 695, 698 227 USPQ 964, 966 (Fed. Cir. 1985). Further, “although produced by a different process, the burden shifts to applicant to come forward with evidence establishing an unobvious difference between the claimed product and the prior art product”, *In re Marosi*, 710 F.2d 798, 802, 218 USPQ 289, 292 (Fed. Cir. 1983). See MPEP 2113.

Therefore, absent evidence of criticality regarding the presently claimed addition of the additive composition to the base fuel simultaneously or after other additives and given that Nelson and Carlson meet the requirements of the claimed composition, Nelson and Carlson clearly meet the requirements of present claims 6 and 7.

Applicant's arguments have been fully considered but they are not persuasive.

Applicant argues there is nothing in Nelson which discloses, teaches or suggests to one skilled in the art how to modify the reference for introducing the alkyl lead and the additive package simultaneously with, or after other additives into the fuel as opposed to adding these components to the fuel before introduction of other additive

packages. Applicant argues that by practicing the above method of addition that the amount of alkyl lead required while maintaining the desired level of anti-knock performance and ORI reduction is realized with lower amounts of alkyl lead when it is mixed into the additive package of the claimed invention.

Applicant has provided no examples to support his argument. The examples set forth in the specification do not show what Applicant is alleging. Furthermore, it would be reasonable to expect that less alkyl lead would be required because the fuel conditioner reduces the deposits in the intake system and combustion chamber thus requiring less octane enhancement.

Applicant argues that Lyben teaches away from the use of the claimed lead compounds.

Lyben teaches that the only scavengers that have enjoyed commercial success have been ethylene dibromide and ethylene dichloride. Lyben teaches that the scavenger of his invention has improved scavenging properties over the previous scavengers. However, he does not teach that his scavengers replaced the commercially successful ethylene dihalides.

Applicant argues that Carlson teaches away from the sole use of the lead compounds claimed by Applicant's invention and how to reduce the amount of these alkyl lead compounds without the addition of other anti-knock compounds.

Applicant's claims are open to the inclusion to other components and are not limited to a single anti-knock compound.

Applicant respectfully traverses these rejections. The key to Applicant's invention, as mentioned above, is providing a leaded motor fuel additive composition for bulk fuel addition. More particularly, this invention relates to a motor fuel additive composition comprising: (a) a fuel conditioner component comprising (i) a polar oxygenated hydrocarbon compound, and (ii) an oxygenated compatibilizing agent; (b) an alkyl lead compound; and (c) a lead scavenger compound for use in bulk production of motor fuels containing alkyl lead allowing lower levels of alkyl lead while improving performance and decreasing ORI.

Amdt. Dated: 6/15/2008  
Reply to Office action of: 12/14/2007

A fair reading of the Nelson ('723) reference, as mentioned above, discloses an additive package for motor fuels having any anti-knock materials previously blended into the base motor fuel before addition of the additive package of Nelson ('723). Because of the unpredictable nature of organic compositions, adding the tetramethyl and the additive package simultaneously with, or after other additives into the fuel as opposed to adding these components to the fuel before introduction of other additive package is not obvious. This is confirmed by the fact that the amount of alkyl lead required while maintaining the desired level of anti-knock performance and ORI reduction is realized with lower amounts of alkyl lead when it is mixed into the additive package of the claimed invention as opposed to being mixed into the fuel before or after mixing in the claimed additive package.

There is nothing in the Nelson ('723) reference which discloses, teaches or suggests to one skilled in the art how to modify the reference to provide for introducing the alkyl lead and the additive package simultaneously with, or after other additives into the fuel as opposed to adding these components to the fuel before introduction of other additive packages.

A fair reading of the Carlson ('088) reference, as mentioned above, discloses the use of aromatic substituted esters as an additional compound to raise the octane number, and help suppress knocking in leaded gasoline fuels (Col. 1, lines 51 – 60). This reference realizes that alkyl lead compounds have a limit to effectiveness that decreases with increased amounts of these alkyl lead compounds in gasoline and the fact that they create deposits in the combustion chambers. Instead of scavenging these deposits this reference teaches to add a substitute octane enhancer in addition to the use of alkyl lead compounds. Thus, this reference clearly teaches away from the sole use of the very lead compounds claimed by Applicant's invention and how to reduce the amount of these alkyl lead compounds without the addition of other anti-knock compounds.

There is nothing in the Carlson ('088) reference which discloses, teaches or suggests to one skilled in the art how to modify the reference to provide for the use of the additive composition of Nelson ('723) or the unexpected ability to reduce the amount of alkyl lead compound required while retaining desired levels of ORI reduction and anti-knock, in combination with a second class of octane enhancer/anti-knock compounds.

The Examiner has stated in response to Applicants' previous arguments that:

Appl. No.: 10/709,866  
Amdt. Dated: 6/15/2008  
Reply to Office action of: 12/14/2007

Applicant argues there is nothing in Nelson which discloses, teaches or suggests to one skilled in the art how to modify the reference for introducing the alkyl lead and the additive package simultaneously with, or after other additives into the fuel as opposed to adding these components to the fuel before introduction of other additive packages. Applicant argues that by practicing the above method of addition that the amount of alkyl lead required while maintaining the desired level of anti-knock performance and ORI reduction is realized with lower amounts of alkyl lead when it is mixed into the additive package of the claimed invention.

Applicant has provided no examples to support his argument. The examples set forth in the specification do not show what Applicant is alleging. Furthermore, it would be reasonable to expect that less alkyl lead would be required because the fuel conditioner reduces the deposits in the intake system and combustion chamber thus requiring less octane enhancement.

Applicant argues that Lyben teaches away from the use of the claimed lead compounds.

Lyben teaches that the only scavengers that have enjoyed commercial success have been ethylene dibromide and ethylene dichloride. Lyben teaches that the scavenger of his invention has improved scavenging properties over the previous scavengers. However, he does not teach that his scavengers replaced the commercially successful ethylene dihalides.

Applicant argues that Carlson teaches away from the sole use of the lead compounds claimed by Applicant's invention and how to reduce the amount of these alkyl lead compounds without the addition of other anti-knock compounds.

Applicant's claims are open to the inclusion to other components and are not limited to a single anti-knock compound.

Applicant respectfully traverses this basis of rejection. Applicants respectfully but strenuously argue that there being no statutory requirement for examples to make a claimed invention valid the fact that Applicants has provided none does not in any way make their invention any less valid. In addition, "...reasonable to expect..." is not a proper basis for rejection either. Instead, a reference must "...disclose or fairly

Appl. No.: 10/709,866  
Amdt. Dated: 6/15/2008  
Reply to Office action of: 12/14/2007

suggest..." within its four corners the claimed invention to which it is applied against. There is clearly no such "...disclosure or fair suggestion..." here. Furthermore, whether a patented invention claims, or has in fact, replaced other inventions in the art from the marketplace is, and never has, created a valid reference where the four corners of the suggested reference do not teach or fairly suggest the claimed invention being examined and where, in fact, the reference teaches directly away from Applicants' claimed invention. Applicants respectfully suggest that the Examiner is improperly applying a reference which in fact teaches and suggests the novelty of Applicants' claimed invention. Finally, claims are always read in the light of the teaching upon which they are based and here, there is no teaching or suggestion of including any other anti-knock compound to the claimed invention. In fact the independent claims specifically call for "A leaded motor fuel additive composition" which clearly limits the claimed invention in this regard.

In view of the remarks herein, and the amendments hereto, it is submitted that this application is in condition for allowance, and such action and issuance of a timely Notice of Allowance is respectfully solicited.

Respectfully submitted,
